Abstract. *Borkhausenia crinnodes* Meyrick, 1912, a species described from Argentina, has been found resident in Beira Litoral, Portugal, constituting its first records in Europe. *Borkhausenia intumescens* Meyrick, 1921, described from South Africa, is shown to be synonymous with *B. crinnodes*, described from Argentina. COI barcode sequencing has shown that a Portuguese specimen has 100% similarity with specimens collected in South Africa. The origin of the Portuguese population remains unclear but it is likely to be connected with timber importation for the paper industry. Male and female genitalia of *B. crinnodes* type and the Portuguese specimens are illustrated and described.

Introduction

Nine specimens of an oecophorid moth have been taken by Jorge Rosete on separate occasions from five different localities in central Portugal between July 2012 and July 2016. The first specimen, a female which appeared to belong to Oecophoridae, was examined in 2013 by Martin Corley. The following year, dissection of a male evidently belonging to the same species confirmed the family placement but could not be recognised as any known European member of that family. The possibility that it was an adventive from another continent was considered more likely than that it was a native of Portugal.

Central Portugal is dominated in many areas by plantations of eucalyptus. This, together with the fact that there are more Oecophoridae species in Australia than in any other continent, gave rise to the consideration that the species might have an Australian origin. Other Australian Oecophori-

dae have arrived in Europe as adventives, such as *Tachystola acroxantha* (Meyrick, 1885) (Clutterbuck 1910; Agassiz 1971) and *Barea asbolaea* (Meyrick, 1883) (Oakes *et al.* 2010). Therefore, the first attempts to identify the Portuguese moths followed this avenue. At the suggestion of Martin Honey, photographs of the female genitalia and the moth were sent to E. D. Edwards at Canberra, who suggested it might be the previously unknown female of one of the undescribed species of the genus *Oncomerista* Common, 2000, since the female of the only described species, *O. ochrophaea* (Meyrick, 1883) has a signum consisting of radiating spines. In 2013, after a male had been found, it became clear that the Portuguese species did not belong to *Oncomerista*. Furthermore, a search of the three volumes on Australian Oecophoridae (Common 1994, 1997, 2000) did not produce any plausible candidate for the Portuguese species.

In 2016, a DNA sample was taken for barcoding. This gave a 100% match on BOLD with three unidentified specimens that had been captured in South Africa. This new information opened up new possibilities. Images of the moth and the genitalia of both sexes were sent to Alexander Lvovsky (Russia), who has a wide knowledge of Old World Oecophoridae. He was able to determine that the Portuguese specimens belong to *Borkhausenia intumescens* Meyrick, 1921, described from Port Elizabeth in South Africa. At the suggestion of AL, MFVC studied the type of the Argentinian *B. crinnodes* Meyrick, 1912 at BMNH. From this it became evident that *Borkhausenia intumescens* is a junior synonym of *B. crinnodes*.

Material and methods

Nine specimens of *B. crinnodes* have so far been captured in Beira Litoral, Portugal by JR (Table 1, Fig. 1), specimens were always seen singly. In addition, the following museum material has been examined:

Borkhausenia crinnodes Meyrick, 1912. Holotype: Argentina: Parana. R. '06 [1906] J.F.G. Clarke male gen. prep. 4765. (BMNH), seen by MFVC.

Borkhausenia intumescens Meyrick, 1921. Two specimens. Lectotype in DNMNH, seen by AL, labelled 'Borkhausenia intumescens M. Type No. 774' 'Port Elizabeth, Fitz Simons 25.12.16, Coll. Janse' '24 81' 'G 8241'. Second specimen in BMNH, South Africa: Cape Province, Port Elizabeth, probably a paratype, but not labelled as such, seen by MFVC.

Table 1. *Borkhausenia crinnodes* specimens captured in Portugal. For each we list the Municipality, locality, the UTM coordinates, date of collection, genitalia preparation code when applicable and collection where the specimens are deposited.

DNA extraction and sequencing

Genomic DNA was extracted from leg tissue (Table 1) using EasySpin Genomic DNA Tissue Kit (Citomed) following manufacturer's protocol. The cytochrome c oxidase I (COI) barcoding fragment was amplified as two overlapping fragments, using two sets of primers. For the first fragment, primers LepF (Hebert *et al.* 2004) and MlepR (Hajibabaei *et al.*, 2006) were used, while primers LepR (Hebert *et al.* 2004) and MlepF (Hajibabaei *et al.* 2006) were used to amplify the second fragment.

Both PCR reactions had 10 µL of final volume, containing 5 µL of Multiplex PCR Master Mix (QIAGEN), 0.4 µM of each primer, and 1–2 µL of DNA. PCR amplification was carried out on a T100 Thermal Cycler (BioRad) using the following conditions: initial denaturation at 95 °C for 15 min; 5 cycles at 95 °C for 30 s, 47 °C for 45 s, 72 °C for 45 s; then 40 cycles at 95 °C for 30 s, 51 °C for 45 s, 72 °C for 45 s; and a final elongation step at 60 °C for 10 min. The barcodes were sequenced in an Illumina Miseq platform, following the approach described by Shokralla *et al.* (2015).

We used OBITools (<https://git.metabarcoding.org/obitools/obitools>) for general sequence processing. Geneious v.6.1.5 (<http://www.geneious.com/>) was used for final sequence assembly. The sequence obtained was blasted against GenBank and BOLD databases. The average divergence (uncorrected p-distance) between the sequence of Portuguese specimen and *Borkhausenia* sp. COI sequences available in GenBank and BOLD was calculated in MEGA v.5.2.1 (Tamura *et al.* 2011).

Results

***Borkhausenia crimnodes* Meyrick, 1912, Trans. ent. Soc. Lond. 1911: 695.**

Figs 2–3

Type locality. Argentina, Paraná.

***Borkhausenia intumescens* Meyrick, 1921, Ann. Transvaal Mus. 8: 99. syn. nov.**

Figs 4–6

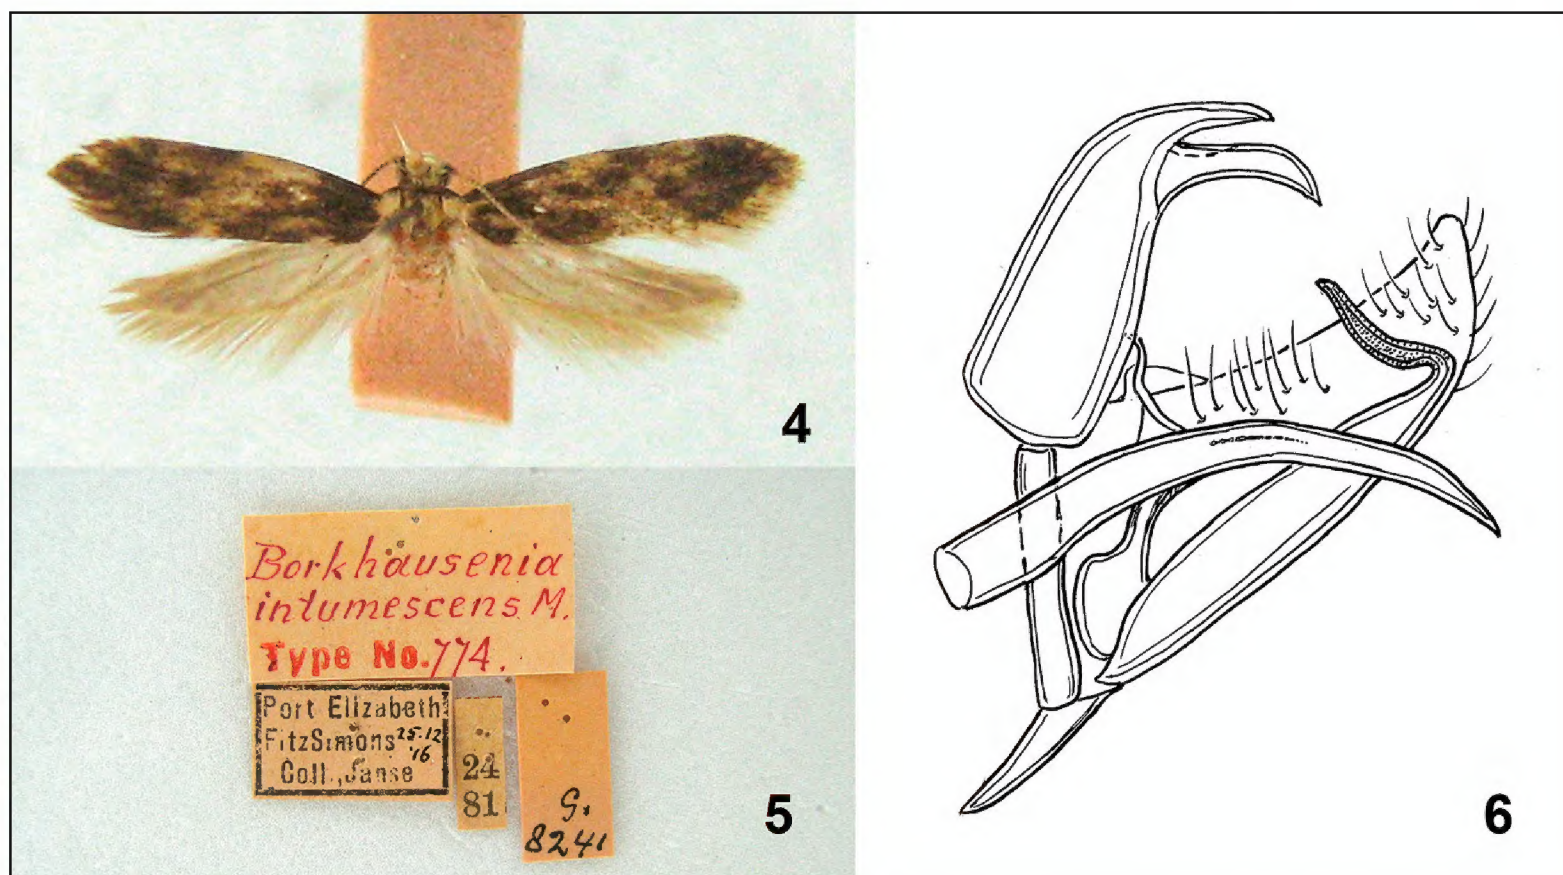

Type locality. South Africa, Port Elizabeth. Justification for the synonymy is elaborated in the section Synonymy below.

Redescription. Meyrick (1912, 1921) described *B. crimnodes* and *B. intumescens* separately. The redescription below is based on Portuguese specimens, but is equally applicable to the two Meyrick types. Male and female genitalia have not been described or documented previously (Figs 2–3, 6–10).

Habitus. Male and female similar (Figs 11–12). Wing length 4.4–6.0 mm; wingspan 9–13 mm. Head cream-coloured. Antenna buff, with light brown bands, scape with a pecten-like row of elongated scales. Ocellus absent. Proboscis present. Labial palp upcurved, creamy white, segment 3

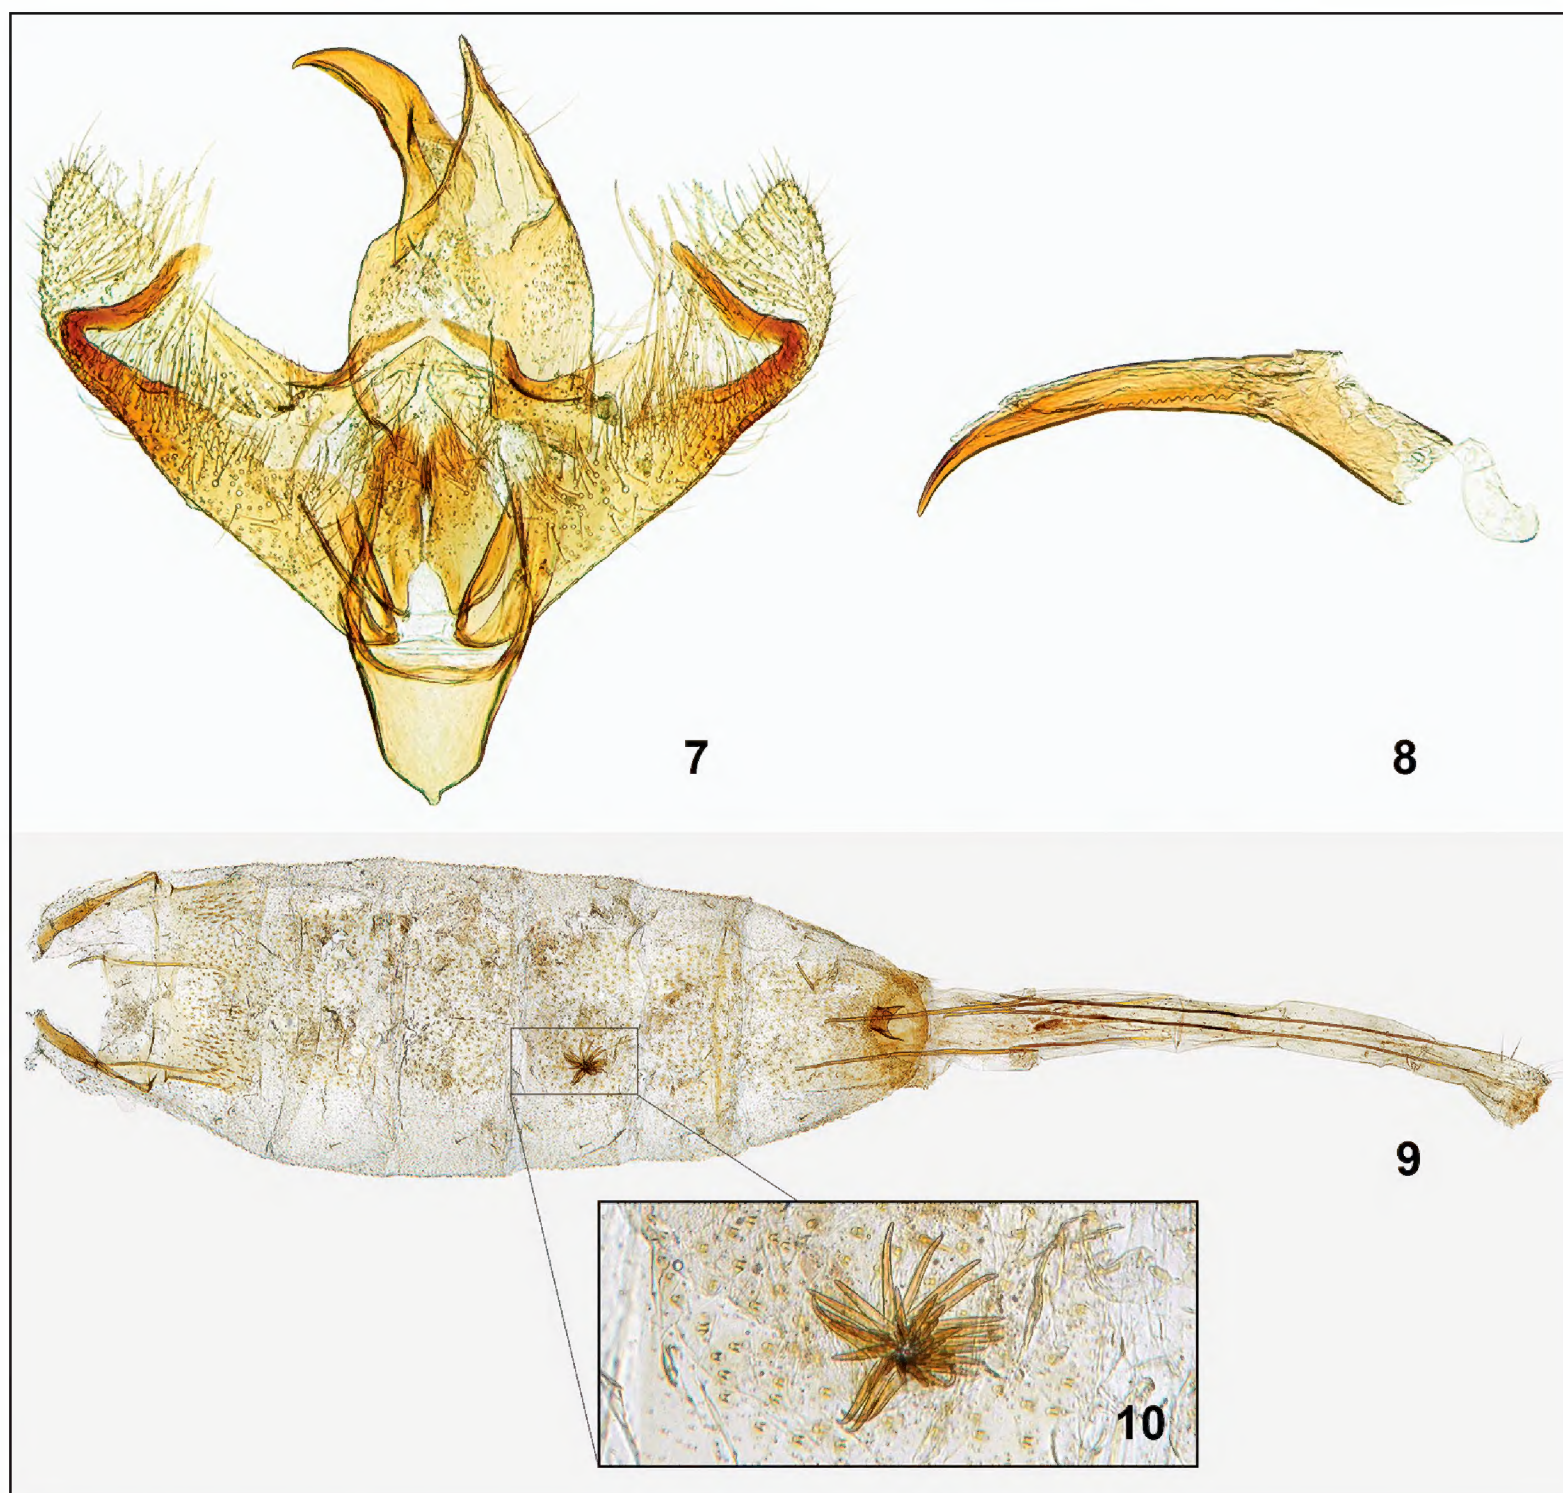

Figures 2–3. Male genitalia of *Borkhausenia crinnodes* Meyrick, 1912, Argentina, Paraná (BMNH). **2.** Genitalia without phallus; **3.** Phallus.

Figures 4–6. *Borkhausenia intumescens* Meyrick, 1921, South Africa, Port Elizabeth. **4.** Lectotype male (DNMNH); **5.** Labels of lectotype; **6.** Male genitalia of lectotype (left valva omitted), A. Lvovsky *del.*

shorter than segment 2, with fuscous base and apex. Thorax creamy ochreous. Forewing elongate, narrow, creamy ochreous with extensive fuscous patches, sometimes mixed creamy ochreous, one patch at base extending to one-third on costa, and to three-fifths on dorsum with irregular outer margin, one in terminal quarter of wing and a small elongate patch along costa at middle; usually three dark fuscous round spots in mid-line, the first and third usually touching the basal and terminal dark patches respectively, the middle spot nearer the costa than the other two, a slightly

Figures 7–10. Genitalia of Portuguese specimens. 7. Male genitalia, without phallus (Portugal, Ansião); 8. Phallus (extreme base missing); 9. Female genitalia (Portugal, Lourical); 10. Signum enlarged.

elongated plical spot is sometimes visible within basal fuscous patch; cilia creamy ochreous. Hindwings light grey. Abdomen ochreous buff.

Venation. Forewing with R4 and R5 stalked; R5 to costa near apex; Cu1 and Cu2 separately from the cell. Hindwing with Rs and M1 separately from the cell; M3 and Cu1 from one point; Cu1 and Cu2 separately from the cell.

Male genitalia (Figs 2–3, 6–8). Uncus narrowed to pointed apex. Gnathos sclerotised, narrowed to pointed apex, extending beyond uncus. Valva with narrow processes at the base of costa forming hemitransstilla; sclerotised process at the distal end of sacculus strongly elbowed at base, with a slight outwards curve in middle, distal part crossing costa of valva perpendicularly. Juxta lobes broad, slightly tapering to hairy apex. Saccus triangular to trapeziform. Phallus slightly curved, cornutus saw-like, two-fifths length of phallus.

Figures 11–12. Male Portuguese specimens: **11.** Lourical, Pombal, Coimbra; **12.** Paúl de Madriz, Soure, Coimbra.

Female genitalia (Figs 9–10). Ovipositor long and narrow. Small antrum sclerotised. Ductus bursae short. Signum flower-like with sclerotised narrow petals.

Variation (Figs 11–12). Some Portuguese specimens have the forewing ground colour more golden ochreous than whitish ochreous. The precise shape of the basal and apical fuscous patches is somewhat variable; the middle dark fuscous spot may be weakly developed.

Synonymy

The male genitalia illustrated in this paper (Figs 2–3, 6–8) appear to show small differences, particularly in the shape of the saccus, and possibly in the cornutus. Other differences between the dissected genitalia of the Portuguese specimens and the type of *B. crimnodes* are artefacts due to differences in the way the genitalia are presented in the preparation. This affects the shape of the valva and the gnathos, mainly because the cover slip of the Clarke preparation of the Argentinian type is less pressed down. The preparation of the type of *B. intumescens* was seen by AL a number of years ago and a drawing of part of it made at the time, which is reproduced here (Fig. 6). It does not show the whole of the saccus and the juxta is obscured by the phallus.

In spite of these differences there are very good reasons for considering the Portuguese specimens and the types of *B. intumescens* and *B. crimnodes* to belong to a single species. The moths are of similar size and have the same habitus (Figs 4, 11, 12). In the male genitalia, the shape of the process at the end of the sacculus, which is very distinct from other species, is similar in the specimens analysed (Figs 2, 6, 7). Differences in the cornutus are explained by the position in which this lies within the phallus; in the Portuguese specimen (Fig. 8) it appears in lateral view where it resembles a saw, while in the other two figures (3 and 6) it is seen edge on and only the points of the teeth are clearly evident. The saccus is clearly broader in the Portuguese preparation than in that of *B. crimnodes* type, but not too much significance can be placed on this character, which sometimes shows some variation in other gelechioid moths. Finally, the Portuguese moth barcoded is 100% identical to three specimens (details below under Molecular analysis) from South Africa which are illustrated in BOLD and have the same habitus as the Portuguese specimens, *B. intumescens* and *B. crimnodes*. We are fully convinced that *B. intumescens*, *B. crimnodes*, and the Portuguese specimens belong to a single species, *B. crimnodes*, of which *B. intumescens* is a junior synonym.

Table 2. Mean (below diagonal) and standard deviation (above diagonal) sequence divergence (uncorrected p-distances) of 658 bp fragment of cytochrome c oxidase I (COI) among pairs of species of *Borkhausenia* with sequences available on BOLD and GenBank.

	<i>B. crimnodes</i>	<i>B. catochopis</i>	<i>B. fuscescens</i>	<i>B. luridicomella</i>	<i>B. minutella</i>

<i>B. minutella</i>	12.2%	13.1%	10.9%	12.2%	

Bionomics

The larval food of *B. crimnodes* is unknown, but is likely to be some sort of dry plant matter or debris, perhaps affected by mould or other fungi. Three specimens were taken from inside the building where JR lives, adjacent to garages. The prevalence of the species in this building is unexplained. One was taken beneath a street light, one from a porch light and three were taken at 160-watt blended mercury vapour light. Individuals have been captured in April, June, July, August, September and October, suggesting that the species is multivoltine in Portugal.

Molecular analysis

The BLAST search in BOLD (Ratnasingham and Hebert 2007) with the 658 bp COI sequence obtained from a Portuguese specimen (Specimen code – INV03258; GenBank Accession number KY053459) yielded 3 records with 100% similarity score. The three corresponding specimens, coded as CCDB-22957-E10, CCDB-22957-E11 and CCDB-22957-F10, are deposited at the National Museum of Natural History, Smithsonian Institution and were collected in Eastern Cape – South Africa. None of the specimens has identification at family level or below. No other *Borkhausenia* species has been listed in 99 first results from the search in the COI Full Database despite the existence of 25 published records. *Borkhausenia* species pairs exhibited high levels of genetic divergence in the COI dataset analysed (uncorrected p-distance ranges 10.9–15.4) (Table 2).

Discussion

At the time of the description of *Borkhausenia crimnodes*, before the use of genitalia characters as a taxonomic tool had become routine practise, many genera of Microlepidoptera were understood in a much wider sense than is now the case. *Borkhausenia* is an example of a genus that once included large numbers of species. More than 268 species were described as *Borkhausenia* species (Bisby *et al.* 2011), but the majority are now considered to belong in other genera, sometimes even in other families. In Common (1994, 1997, 2000) all of the approximately 40 *Borkhausenia* species described from Australia were placed in other genera. Due to lack of revisionary work elsewhere it is not currently possible to be sure how many species remain in the genus. The morphological and genetic distinctness of *B. crimnodes* raises the question of whether it should still be placed in *Borkhausenia*. Comparison of male and female genitalia with those of other European *Borkhausenia* species [*B. fuscescens* (Haworth, 1828), *B. minutella* (Linnaeus, 1758) (type species), *B. luridicomella* (Herrich-Schäffer, 1856), *B. nefrax* Hodges, 1974] has been made. The following

characters are shared by *B. crimnodes* and the European species: gnathos longer than uncus, transtilla interrupted in the middle, sacculus ending in a process that partially crosses the valva, a single cornutus in the phallus (male), and the long telescopic ovipositor (female). One distinct feature of *B. crimnodes* that is not shared by the European species is the presence of a signum, which is furthermore of a form that is unusual in the family. Likewise, the cornutus is quite different from the cornuti in the European *Borkhausenia* species. The male genitalia characters (gnathos longer than uncus, divided transtilla and distal process of sacculus crossing the valva) do not of themselves indicate close relationship between these species, particularly as the last two characters can be found in other families of Gelechioidea.

Querying of the BOLD database for *Borkhausenia* species indicates that the few species which have barcode available on BOLD and GenBank (n=5) are not closely related to one another, exhibiting more than 10% divergence between analysed species. Possibly the genus *Borkhausenia*, from which many species have already been removed, is still polyphyletic and its taxonomy certainly requires further research. In the absence of a world revision of this and related genera, we retain *B. crimnodes* in *Borkhausenia*.

B. crimnodes was described from Paraná in the province of Entre Rios, Argentina. Paraná is by the Paraná River, about 250 kilometres inland from Buenos Aires. *B. intumescens* was described from Port Elizabeth, Eastern Cape, South Africa. It is also present inland in the mountains. Those *Borkhausenia* species with known larvae feed on plant detritus, so this is likely to be the case also with *B. crimnodes*. Species with this larval behaviour are readily transported by human trade across considerable distances and resulting adults can readily find suitable food sources for oviposition. Examples include several species of *Blastobasis* originally from Madeira and now well established in the British Isles (Agassiz 1996) and *B. decolorella* (Wollaston, 1858) in continental Portugal (Corley 2015).

Since *B. crimnodes* is so far recorded from nowhere else in Europe, it would appear to have been accidentally introduced into Portugal, perhaps from South Africa or Argentina, although the possibility that it might be established elsewhere in the world cannot be ruled out. With species that are readily transported long distances by human agency, it can be difficult to establish the true country of origin. While it is puzzling that the known Portuguese sites are in Beira Litoral, remote from the main ports or airports of Lisboa and Porto, there is a smaller port at Figueira da Foz that might have provided a means of entry for *Borkhausenia crimnodes*. It is known that two paper mills in the region import timber from South America through Figueira da Foz port.

Acknowledgements

We are most grateful to all those who have helped towards solving the identity of *B. crimnodes*. David Lees in particular, but also Klaus Sattler and Martin Honey at BMNH gave valuable assistance, Ted Edwards made useful suggestions regarding Australian Oecophoridae, Brian Goodey did an excellent job of photographing MFVC's genitalia preparations, Ernestino Maravalhas prepared the map, Joana Veríssimo processed the specimens for barcoding. This project has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement no. 668981. SF is supported by Fundação para a Ciência e Tecnologia through project grant ExpandTree (FCT-ANR/BIA-BIC/0010/2013) co-funded by the European Program COMPETE: FCOMP-01-0124-FEDER-019772 and ALL is supported by Russian state research project no. 01201351189 and the Russian Foundation for Basic Research, grant no. 14-04-00770.
